Abstract. To accurately determine the beginning and the end of voltage sags is very important for the actuation of a system that is connected to the grid and must have ride-through capability. This paper analyses four voltage sag detection methods, comparing both detection speed and reliability, not presenting false detections and providing a consistent signal during all the gap duration. In particular, it has been analysed the behaviour of the detection methods when voltage waveforms present harmonics due to power electronics switching.

Key words: Voltage dips, Voltage sag detection, Power quality, Wind energy.

1. Introduction

The increase in renewable energy use in electrical energy generation makes necessary the compliance with some technical requirements in order not to compromise the operation of the electric system.

These connection requirements affect all the aspects related to the quality of the energy sent to the grid [1] and the behaviour of the system when grid perturbations occur. Voltage sags are one of the many power quality related problems the industrial process sector has to face, and they are one of the most severe. They consist on a reduction of the voltage at a customer position with duration between one cycle and half a second [2].

This paper compares the behaviour of four voltage sag detection methods when facing three, two or single phase faults, according to Spanish Operation Procedure 12.3. The aim of the paper is to determine the best detection method to be used in the control of the grid connection inverter of a variable-speed squirrel-cage wind turbine connected to a weak grid, in order to provide it with voltage sag ride-through capability.

2. Simulated methods

Several voltage detection methods have been documented for use in various voltage compensation schemes. In this paper, the following methods are simulated and evaluated.

   a) Applying the Fourier Transform to Each Phase

   This method gives the amplitude and phase of the main component of the utility voltage, but its main drawback is the need for at least half period (10 ms) in order to have an accurate result, which generates a significant delay in the response of the system to a voltage sag.

   b) Numerical Matrix Sag Detection Method [3]

   The method calculates the magnitude and phase of the different harmonics present in the supply voltages. It is applied to each phase independently and as thus can monitor the start or end of the sag, its depth and any phase jump. In order to provide a unique solution, the number of equations to be solved is twice the number of harmonics detected in the supply. Solving these equations, the magnitude and phase of the different harmonics can be determined.

   c) Peak Value Evaluation Method [4]

   This method determines the variation of the peak value of the voltages. Its mains drawback is the need for half a period in order to detect the gap.
This method gives a correct measure of the evolution of the observed magnitude since it expresses the energy content of the signal.

3. Detection method comparison

The selected system must be able to detect voltage sags as quickly as possible and be as immune as possible to the presence of harmonics in the grid voltage. Precision and fast detection are essential features for the detection method, in order for the system to ride through voltage sags.

Since the simulated system is connected to a weak grid, it is highly influenced by the harmonic content, and one of the goals of the paper is to determine which detection method is more robust.

Several simulations have been carried out for different ripple magnitude in the voltage waveform:
- pure sinusoidal waveform
- waveform showing distortion introduced by a rectifying bridge.
- waveform showing a 5% ripple and the distortion introduced by a rectifying bridge.
- waveform showing a 10% ripple and the distortion introduced by a rectifying bridge.
- waveform showing a 20% ripple and the distortion introduced by a rectifying bridge.

These simulations show that the Matrix method is the more sensitive to harmonics, so grid voltages have been filtered using a second order low-pass filter with a cut-off frequency of 100 Hz.

Fig. 1 shows voltage amplitudes provided by the matrix method for the unfiltered voltage on a weak grid feeding a diode bridge. Large variation due to harmonics indicates the need for adequate filtering.

Fig. 2. Detection time for the different methods: Fourier (yellow), Matrix (pink), peak value (blue), RMS value (red).

The following table shows the voltage gap detection time and the required filters in order not to have incorrect detections.

<table>

4. Conclusions

The paper describes simulations of different voltage sag detection techniques and, among them, the best one is the matrix method, even having to use filtering, because it provides a consistent detection signal and gives the fastest response.

Besides, this method provides phase information, required for the inverter control algorithm in order to comply with Operation Procedure 12.3.
